Lab 2 Regression Lab

Oleg Ananyev, Oren Carmeli, Romain Hardy, Sam Rosenberg

Fall 2021

Introduction

The Google Play Store is one of the major hubs for applications for Android mobile phone and tablet users. Users are can download any app on the Google Play Store for personal consumption, however in a sea of tens of thousands of apps or more, we would like to determine the drivers for app downloads. Given that most phones have limited screen real estate and they are intended for light computational tasks, getting an app in-front of a consumer is a challenging proposition as developers have several factors going against them (e.g., vast quantity of duplicate apps, limited screen real estate for ads, limited screen time by most users, etc.). With this in mind - we would like to determine the key drivers to app downloads on the Google Play Store using a fairly robust dataset from Kaggle from 2019 that contains records of ~10,000 apps available from the Google Play Store.

Statista reports there were \sim 220 billion mobile application downloads globally in 2020. Another study found that \sim 70% of all US digital media is spent on mobile applications. Mobile app usage is becoming the focal interaction medium in which organizations can engage and help their customers and it is useful for organizations to further understand drivers that help lead to more mobile application usage and a better customer experience. This dataset allows to analyze the potential levers to app downloads such as average review rating, price, app size, app category, etc. With this dataset, we will plan to build a statistical linear model to determine the importance (or unimportance) of each of these variables on app downloads. Given our beliefs on what causes individuals to download a mobile application we believe there are some important ommitted variables that can influence app downloads such as brand awareness from marketing campaigns, the size of existing customer bases, seasonality, and individual life circumstances. Despite these limitations, we believe the dataset provides useful information to evaluate the importance of other characteristics outside of these external factors.

Lab 2 Intructions: Your introduction should present a research question and explain the concept that you're attempting to measure and how it will be operationalized. This section should pave the way for the body of the report, preparing the reader to understand why the models are constructed the way that they are. It is not enough to simply say, "We are looking for product features that enhance product success." Your introduction must do work for you, focusing the reader on a specific measurement goal, making them care about it, and propelling the narrative forward. This is also a good time to put your work into context, discuss cross-cutting issues, and assess the overall appropriateness of the data.

Data and Research Design

Lab 2 Intructions: After you have presented the introduction and the concepts that are under investigation, what data are you going to use to answer the questions? What type of research design are you using? What type of models are you going to estimate, and what goals do you have for these models?

Model Building

Lab 2 Intructions: You will next build a set of models to investigate your research question, documenting your decisions. Here are some things to keep in mind during your model building process: 1. What do you want to measure? Make sure you identify one, or a few, variables that will allow you to derive conclusions relevant to your research question, and include those variables in all model specifications. How are the variables that you will be modeling distributed? Provide enough context and information about your data for your audience to understand whatever model results you will eventually present. 2. What covariates help you achieve your modeling goals? Are there problematic covariates? either due to collinearity, or because they will absorb some of a causal effect you want to measure? 3. What transformations, if any, should you apply to each variable? These transformations might reveal linearities in the data, make our results relevant, or help us meet model assumptions. 4. Are your choices supported by exploratory data analysis (EDA)? You will likely start with some general EDA to detect anomalies (missing values, top-coded variables, etc.). From then on, your EDA should be interspersed with your model building. Use visual tools to guide your decisions. You can also leverage statistical tests to help assess whether variables, or groups of variables, are improving model fit. At the same time, it is important to remember that you are not trying to create one perfect model. You will create several specifications, giving the reader a sense of how robust (or sensitive) your results are to modeling choices, and to show that you're not just cherry-picking the specification that leads to the largest effects. At a minimum, you need to estimate at least three model specifications: The first model you include should include only the key variables you want to measure. These variables might be transformed, as determined by your EDA, but the model should include the absolute minimum number of covariates (usually zero or one covariate that is so crucial it would be unreasonable to omit it). Additional models should each be defensible, and should continue to tell the story of how product features contribute to product success. This might mean including additional right-hand side features to remove omitted variable bias identified by your casual theory; or, instead, it might mean estimating a model that examines a related concept of success, or a model that investigates a heterogeneous effect. These models, and your modeling process should be defensible, incremental, and clearly explained at all points. Your goal is to choose models that encircle the space of reasonable modeling choices, and to give an overall understanding of how these choices impact results.

Model Limitations

5a. Statistical limitations of your model

Lab 2 Intructions: As a team, evaluate all of the large sample model assumptions. However, you do not necessarily want to discuss every assumption in your report. Instead, highlight any assumption that might pose significant problems for your analysis. For any violations that you identify, describe the statistical consequences. If you are able to identify any strategies to mitigate the consequences, explain these strategies. Note that you may need to change your model specifications in response to violations of the large sample model.

5b. Structural limitations of your model

Lab 2 Intructions: What are the most important *omitted variables* that you were not able to measure and include in your analysis? For each variable you name, you should *reason about the direction of bias* caused by omitting this variable and whether the omission of this variable calls into question the core results you are reporting. What data could you collect that would resolve any omitted variables bias?

Results

Lab 2 Intructions: You should display all of your model specifications in a regression table, using a package like **stargazer** to format your output. It should be easy for the reader to find the coefficients that represent key effects near the top of the regression table, and scan horizontally to see how they change from specification to specification. Make sure that you display the most appropriate standard errors in your table. In your text, comment on both *statistical significance* and practical significance. You may want to include statistical tests besides the standard t-tests for regression coefficients. Here, it is important that you make clear to your audience the practical significance of any model results. How should the product change as a result of what you have discovered? Are there limits to how much change you are proposing? What are the most important results that you have discovered, and what are the least important?

Conclusion

Lab 2 Intructions: Make sure that you end your report with a discussion that distills key insights from your estimates and addresses your research question
